## 1 What is a Database?

### 1.1 Databases

Simply, **database** is a collection of information.

**Fields** The individual kinds of information are organized into **columns**.

**Records** Each set of information is organized into **rows**.

**Table** Fields and records make up a **table**.

**Database** One or more tables make up a **database**.

The rules that regulate rules and layouts of the database are called the "*schema*" of the database.

## 1.2 Databases vs. Spreadsheets

While both databases and spreadsheets have fields and records:

- Database tables can have specific relationships to each other.
- Databases allow us to manage data and ask questions about data.

## 2 Why Use a Database

Databases let us work with large amounts of data easily. They offer security features to control access to information, and help to reduce redundancy.

## 3 The Client-Server Model

All relational databases operate on the **client-server model**. This means that there's two components that work together to make a complete system.

**Database Server** Performs all relational database management tasks. This is where data is structured, stored, and secured.

**Interface Client** Whether it's graphical or text-based, it allows users to connect and control activities on the server.

### 3.1 Benefits of the Client-Server Model

This system excels at allowing a tailored-system to suit particular needs.

1. Database servers can accept connections from many simultaneous clients.
2. A single client can connect to multiple servers.
3. Most RDBMSs come with preferred client direct from the same vendor.
4. Third-party clients are often available though.

## 4 Relational Database Management Systems

Relational Database Management Systems, or **RDMBS** for short, gives you the tools that you need in order to build database to meet your unique set of requirements.

### 4.1 Data Structures

- Create tables
- Define column parameters
- Formalize relationships
- Create data validation rules

### 4.2 Data Storage

- Organize values in tables
- Build and search indexes
- Maintain redundant data
- Regular backups

### 4.3 Data Security

- Control access
- Manage user login
- Keeps logs for auditing

These are three main responsibilities for an **RDBMS**.

### 4.4 DB Scope

- Desktop
- Server
- Cloud

Depending on your needs, you can choose the scope you want your database to cover.

## 5 Storing Data Efficiently

By splitting data efficiently, you can minimize the amount of space you need while maximizing the granularity in your organization.

## 6 Relational DB

A specific type of database where data is:

- Structured into tables. Rows/records and columns/fields.
- With explicitly defined relationships between tables.

Keys consisting of one or more fields, are used to identify records.

- A primary key uniquely identifies a record
- a foreign key defines a relationship between two tables by referring to a record in a different table

## 7 Structured Query Language

- The programming language of relational databases.
- Developed in the 1970's
- Interface to using the features provided by the RDBMS

**DML** Data Manipulation Language (focus for semester)

**DDL** Data Definition Language

**DCL** Data Control Language
